Part I

Introduction: quantum computing...
the end of the world as we know it?

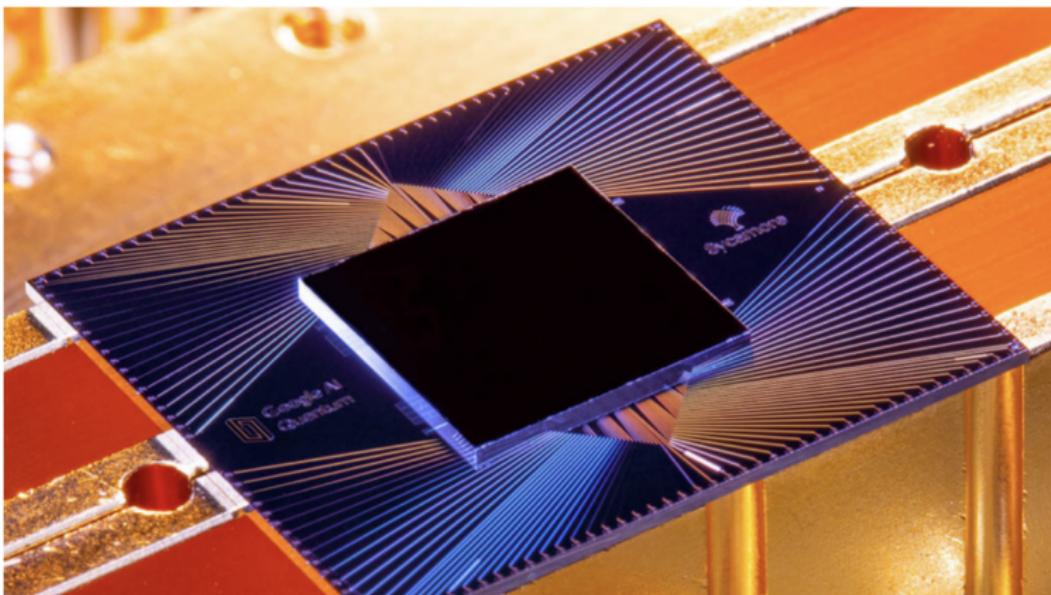

I, for one, welcome our new quantum overlords

NEWS

QUANTUM PHYSICS

Google officially lays claim to quantum supremacy

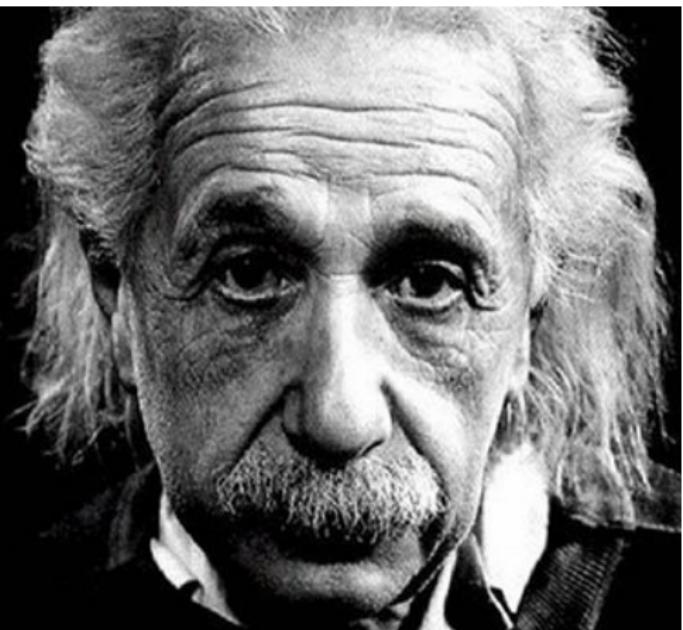

A quantum computer reportedly beat the most powerful supercomputers at one type of calculation

Philosophy of the course

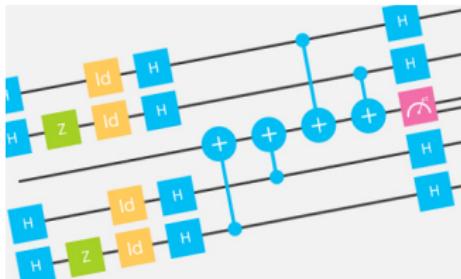

If you can't
explain it to a
computer
you don't
understand it
yourself.

ALBERT EINSTEIN

Tools and resources

- Jupyter Notebooks
 - Web application to create and execute notebooks that include code, images, text and formulas
 - They can be used locally (Anaconda) or in the cloud (mybinder.org, Google Colab...)
- IBM Quantum Experience
 - Free online access to quantum simulators (up to 32 qubits) and **actual quantum computers** (1, 5 and 15 qubits) with different topologies
 - Programmable with a visual interface and via different languages (python, qasm, Jupyter Notebooks)
 - Launched in May 2016
 - <https://quantum-computing.ibm.com/>

Tools and resources (2)

- Quirk
 - Online simulator (up to 16 qubits)
 - Lots of different gates and visualization options
 - <http://algassert.com/quirk>
- D-Wave Leap
 - Access to D-Wave quantum computers
 - Ocean: python library for quantum annealing
 - Problem specific (QUBO, Ising model...)
 - <https://www.dwavesys.com/take-leap>

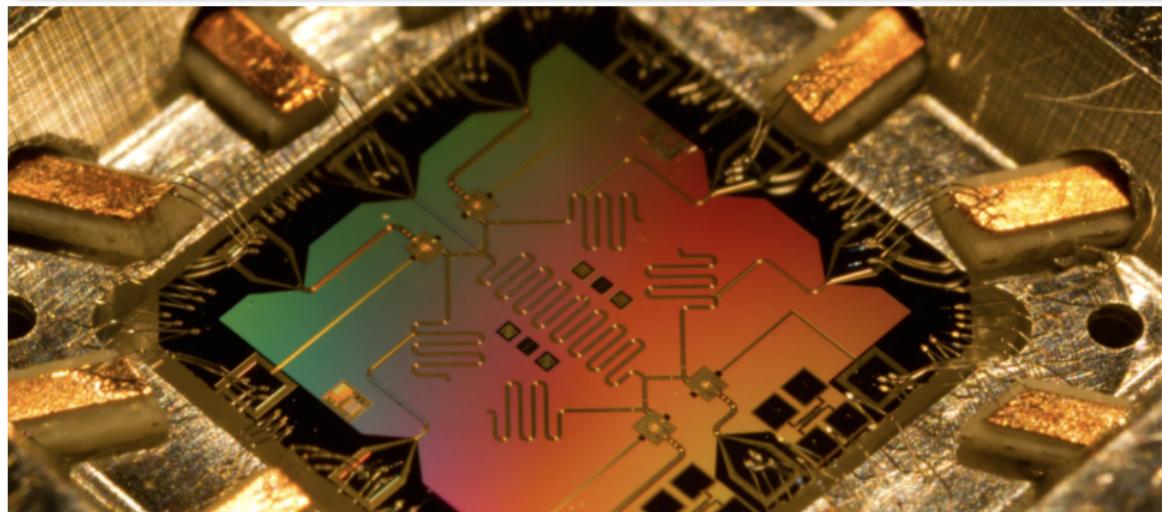

The shape of things to come

What is quantum computing?

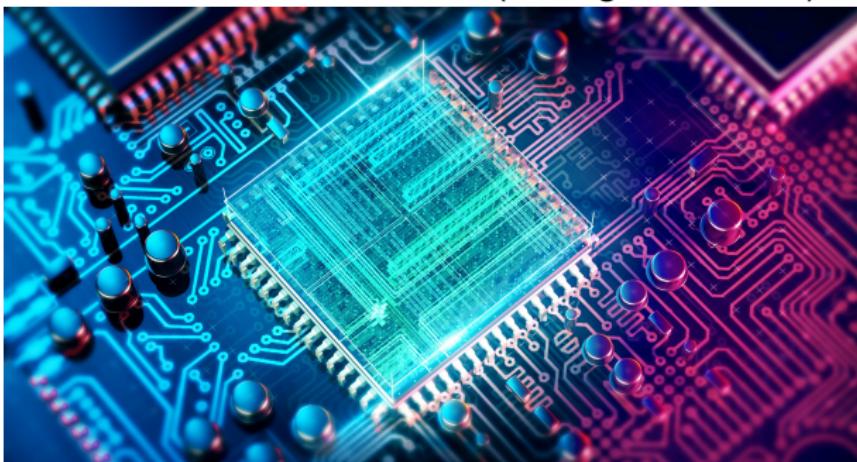

Quantum computing

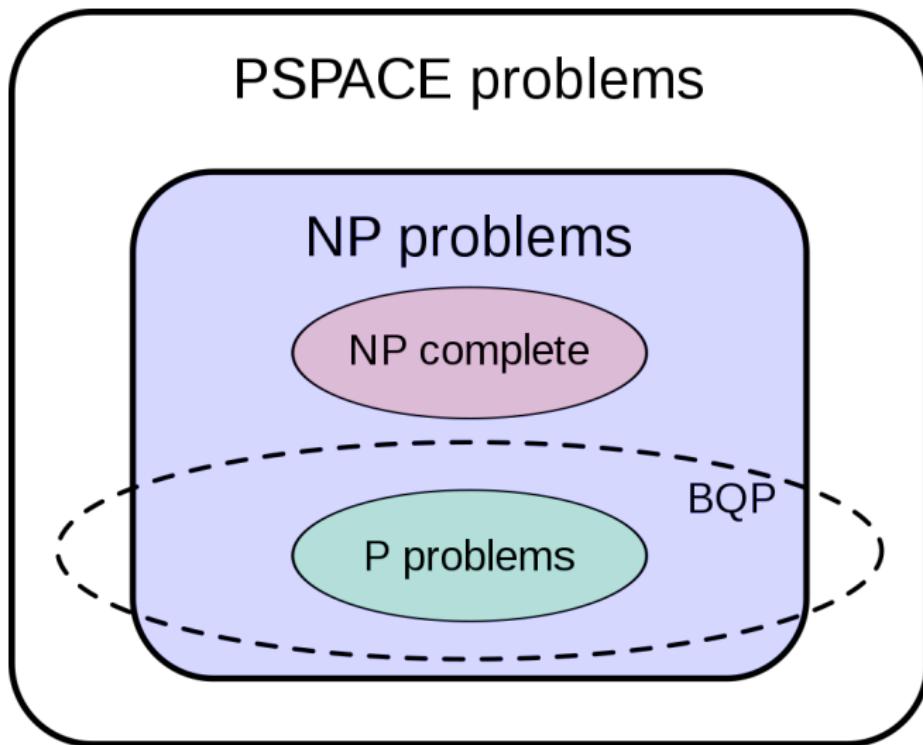

Quantum computing is a computing paradigm that exploits quantum mechanical properties (superposition, entanglement, interference...) of matter in order to do calculations

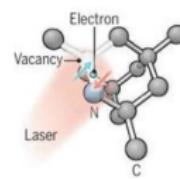

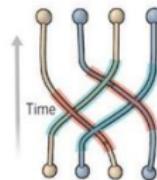

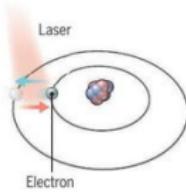

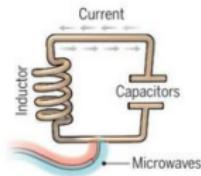

Models of quantum computing

- There are several models of quantum computing (they're all equivalent)
 - Quantum Turing machines
 - **Quantum circuits**
 - Measurement based quantum computing (MBQC)
 - Adiabatic quantum computing
 - Topological quantum computing
- Regarding their **computational capabilities**, they are equivalent to classical models (Turing machines)

What technologies are used to build quantum computers?

Superconducting loops

Company support

Google, IBM, Quantum Circuits

Trapped ions

ionQ

Silicon quantum dots

Intel

Topological qubits

Microsoft,
Bell Labs

Diamond vacancies

Quantum Diamond
Technologies

Pros

Fast working. Build on existing semiconductor industry.

Very stable. Highest achieved gate fidelities.

Stable. Build on existing semiconductor industry.

Greatly reduce errors.

Can operate at room temperature.

Cons

Collapse easily and must be kept cold.

Slow operation. Many lasers are needed.

Only a few entangled. Must be kept cold.

Existence not yet confirmed.

Difficult to entangle.

What is a quantum computer like?

The Sounds of IBM: IBM Q

Programming a quantum computer

- Different frameworks and programming languages:
 - qasm
 - Qiskit (IBM)
 - Cirq (Google)
 - Forest/pyquil (Rigetti)
 - Q# (Microsoft)
 - Ocean (D-Wave)
 - ...
- Most of them for quantum circuit specification

The screenshot shows the QISKit interface with two main panes. The left pane displays QISKit QASM code:

```
1 OPENQASM 2.0;
2 include "qelib1.inc";
3 qreg q[3];
4 creg c[1];
5 creg c[1];
6 creg c[1];
7
8 gate post q ( )
9 u(0.5,0.2,0.1) q[0];
10 h q[1];
11 cx q[1],q[2];
12 barrier q1;
13 cx q[0],q[1];
14 h q[0];
15 measure q[0] -> c0[0];
16 measure q[1] -> c1[0];
17 if(c0==1) z q[2];
18 if(c1==1) x q[2];
19 post q[2];
20 measure q[2] -> c2[0];
21
22
```

The right pane shows the corresponding quantum circuit diagram with three qubits (q[0], q[1], q[2]) and three classical bits (c0, c1, c2). The circuit includes a rotation gate U, a Hadamard gate H, a CNOT gate between q[1] and q[2], a barrier, another CNOT gate, and an if-block controlled by c0 and c1.

What are the elements of a quantum circuit?

- Every computation has three elements: data, operations and results
- In quantum circuits:
 - Data = **qubits**
 - Operations = **quantum gates** (unitary transformations)
 - Results = **measurements**

Part II

One-qubit systems: one qubit to rule them all

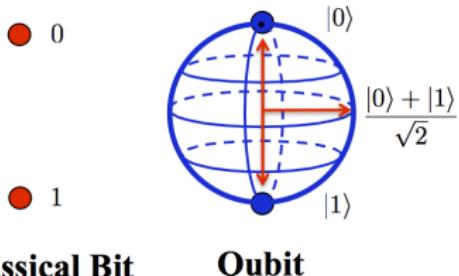

What is a qubit?

- A classical bit can take two different values (0 or 1). It is discrete.
- A qubit can “take” **infinitely** many different values. It is continuous.
- Qubits live in a **Hilbert vector space** with a basis of two elements that we denote $|0\rangle$ y $|1\rangle$.
- A generic qubit is in a **superposition**

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$$

where α and β are **complex numbers** such that

$$|\alpha|^2 + |\beta|^2 = 1$$

Measuring a qubit

- The way to know the value of a qubit is to perform a measurement. However
 - The result of the measurement is random
 - When we measure, we only obtain one (classical) bit of information
- If we measure the state $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$ we get 0 with probability $|\alpha|^2$ and 1 with probability $|\beta|^2$.
- Moreover, the new state after the measurement will be $|0\rangle$ or $|1\rangle$ depending of the result we have obtained (wavefunction collapse)
- We cannot perform several independent measurements of $|\psi\rangle$ because we cannot copy the state (**no-cloning theorem**)

The Bloch sphere

- A common way of representing the state of a qubit is by means of a point in the surface of the Bloch sphere
- If $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$ with $|\alpha|^2 + |\beta|^2 = 1$ we can find angles γ, δ, θ such that

$$\alpha = e^{i\gamma} \cos \frac{\theta}{2}$$

$$\beta = e^{i\delta} \sin \frac{\theta}{2}$$

- Since an overall phase is physically irrelevant, we can rewrite

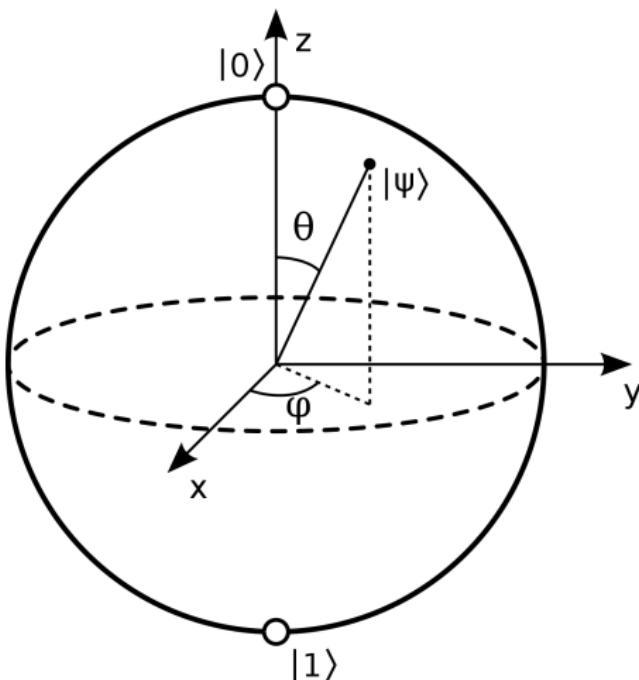

$$|\psi\rangle = \cos \frac{\theta}{2}|0\rangle + e^{i\varphi} \sin \frac{\theta}{2}|1\rangle$$

with $0 \leq \theta \leq \pi$ and $0 \leq \varphi < 2\pi$.

The Bloch sphere (2)

- From $|\psi\rangle = \cos \frac{\theta}{2} |0\rangle + e^{i\varphi} \sin \frac{\theta}{2} |1\rangle$ we can obtain spherical coordinates for a point in \mathbb{R}^3

$$(\sin \theta \cos \varphi, \sin \theta \sin \varphi, \cos \theta)$$

What are quantum gates?

- Quantum mechanics tells us that the evolution of an isolated state is given by the Schrödinger equation

$$H(t)|\psi(t)\rangle = i\hbar \frac{\partial}{\partial t}|\psi(t)\rangle$$

- In the case of quantum circuits, this implies that the operations that can be carried out are given by unitary matrices. That is, matrices U of complex numbers verifying

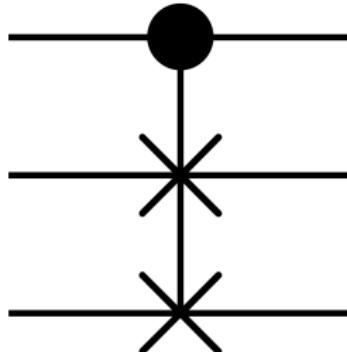

$$UU^\dagger = U^\dagger U = I$$

where U^\dagger is the conjugate transpose of U .

- Each such matrix is a possible quantum gate in a quantum circuit

Reversible computation

- As a consequence, all the operations have an inverse:
reversible computing
- Every gate has the same number of inputs and outputs
- We cannot directly implement some classical gates such as *or*, *and*, *nand*, *xor*...
- But we can simulate any classical computation with small overhead
- Theoretically, we could compute without wasting energy
(Landauer's principle, 1961)

One-qubit gates

- When we have just one qubit $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$, we usually represent it as a column vector $\begin{pmatrix} \alpha \\ \beta \end{pmatrix}$
- Then, a one-qubit gate can be identified with a matrix $U = \begin{pmatrix} a & b \\ c & d \end{pmatrix}$ that satisfies

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \bar{a} & \bar{c} \\ \bar{b} & \bar{d} \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}$$

where $\bar{a}, \bar{b}, \bar{c}, \bar{d}$ are the conjugates of complex numbers a, b, c, d .

Action of a one-qubit gate

- A state $|\psi\rangle = \alpha|0\rangle + \beta|1\rangle$ is transformed into

$$\begin{pmatrix} a & b \\ c & d \end{pmatrix} \begin{pmatrix} \alpha \\ \beta \end{pmatrix} = \begin{pmatrix} a\alpha + b\beta \\ c\alpha + d\beta \end{pmatrix}$$

that is, into the state $|\psi\rangle = (a\alpha + b\beta)|0\rangle + (c\alpha + d\beta)|1\rangle$

- Since U is unitary, it holds that

$$|(a\alpha + b\beta)|^2 + |(c\alpha + d\beta)|^2 = 1$$

The X or NOT gate

- The X gate is defined by the (unitary) matrix

$$\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}$$

- Its action (in quantum circuit notation) is

$$|0\rangle \xrightarrow{\boxed{X}} |1\rangle$$

$$|1\rangle \xrightarrow{\boxed{X}} |0\rangle$$

that is, it acts like the classical NOT gate

- On a general qubit its action is

$$\alpha |0\rangle + \beta |1\rangle \xrightarrow{\boxed{X}} \beta |0\rangle + \alpha |1\rangle$$

The Z gate

- The Z gate is defined by the (unitary) matrix

$$\begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}$$

- Its action is

$$|0\rangle \xrightarrow{\boxed{Z}} |0\rangle$$

$$|1\rangle \xrightarrow{\boxed{Z}} -|1\rangle$$

The H or Hadamard gate

- The H or Hadamard gate is defined by the (unitary) matrix

$$\frac{1}{\sqrt{2}} \begin{pmatrix} 1 & 1 \\ 1 & -1 \end{pmatrix}$$

- Its action is

$$|0\rangle \xrightarrow{H} \frac{|0\rangle + |1\rangle}{\sqrt{2}}$$

$$|1\rangle \xrightarrow{H} \frac{|0\rangle - |1\rangle}{\sqrt{2}}$$

- We usually denote

$$|+\rangle := \frac{|0\rangle + |1\rangle}{\sqrt{2}}$$

and

$$|-\rangle := \frac{|0\rangle - |1\rangle}{\sqrt{2}}$$

Other important gates

- Y gate

$$\begin{pmatrix} 0 & -i \\ i & 0 \end{pmatrix}$$

- S gate

$$\begin{pmatrix} 1 & 0 \\ 0 & e^{i\frac{\pi}{2}} \end{pmatrix}$$

- T gate

$$\begin{pmatrix} 1 & 0 \\ 0 & e^{i\frac{\pi}{4}} \end{pmatrix}$$

- The gates X , Y and Z are also called, together with the identity, the Pauli gates. An alternative notation is σ_X , σ_Y , σ_Z .

Rotation gates

- We can define the following rotation gates

$$R_X(\theta) = e^{-i\frac{\theta}{2}X} = \cos \frac{\theta}{2}I - i \sin \frac{\theta}{2}X = \begin{pmatrix} \cos \frac{\theta}{2} & -i \sin \frac{\theta}{2} \\ -i \sin \frac{\theta}{2} & \cos \frac{\theta}{2} \end{pmatrix}$$

$$R_Y(\theta) = e^{-i\frac{\theta}{2}Y} = \cos \frac{\theta}{2}I - i \sin \frac{\theta}{2}Y = \begin{pmatrix} \cos \frac{\theta}{2} & -\sin \frac{\theta}{2} \\ \sin \frac{\theta}{2} & \cos \frac{\theta}{2} \end{pmatrix}$$

$$R_Z(\theta) = e^{-i\frac{\theta}{2}Z} = \cos \frac{\theta}{2}I - i \sin \frac{\theta}{2}Z = \begin{pmatrix} e^{-i\frac{\theta}{2}} & 0 \\ 0 & e^{i\frac{\theta}{2}} \end{pmatrix} \equiv \begin{pmatrix} 1 & 0 \\ 0 & e^{i\theta} \end{pmatrix}$$

- Notice that $R_X(\pi) \equiv X$, $R_Y(\pi) \equiv Y$, $R_Z(\pi) \equiv Z$,
 $R_Z(\frac{\pi}{2}) \equiv S$, $R_Z(\frac{\pi}{4}) \equiv T$

Using rotation gates to generate one-qubit gates

- For any one-qubit gate U there exist a unit vector $r = (r_x, r_y, r_z)$ and an angle θ such that

$$U \equiv e^{-i\frac{\theta}{2}r \cdot \sigma} = \cos \frac{\theta}{2} I - i \sin \frac{\theta}{2} (r_x X + r_y Y + r_z Z)$$

- For instance, choosing $\theta = \pi$ and $r = (\frac{1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}})$ we can see that

$$H \equiv e^{-i\frac{\theta}{2}r \cdot \sigma} = -i \frac{1}{\sqrt{2}} (X + Z)$$

- Additionally, it can also be proved that there exist angles α , β and γ such that

$$U \equiv R_Z(\alpha)R_Y(\beta)R_Z(\gamma)$$

Hello, quantum world!

- Our very first quantum circuit!

- After applying the H gate the qubit state is

$$\frac{|0\rangle + |1\rangle}{\sqrt{2}}$$

- When we measure, we obtain 0 or 1, each with 50% probability: we have a circuit that generates perfectly uniform random bits!
